Abstract

The thermal and acoustic insulation of individual building elements such as walls, windows and systems for roller shutters significantly affects the thermal and acoustic insulation of a building. This paper considers the acoustic and thermal performance of the individual elements evaluated in laboratory with simulation of both the façade sound reduction index and thermal transmittance of a typical room. The scope of this work is to verify if there are any correlations between acoustic and thermal performance; for this reason, 4 types of opaque wall, 3 window systems for roller shutters and 5 windows for a total of 60 façade configurations have been considered and combined.

1. Introduction

The correct acoustic and thermal design of a building is of fundamental importance for increasing indoor comfort.

Many studies have been carried out regarding acoustic and thermal comfort (Fabbri et al., 2014; Granzotto, 2021; Tronchin et al., 2018; Tronchin et al., 2021), façade acoustic insulation (Hua et al., 2021; Jagniatinskis et al., 2021) and thermal insulation (Theodosiou et al., 2019). Other studies comparing acoustic and thermal characteristics of walls can be found (Di Bella et al., 2014; Di Bella et al., 2015). Sound insulation is one important factor for façade performance optimization. As an example, Ryu et al. (2010) proved that the sound insulation of a building façade influenced indoor annoyance due to transportation noise and the frequency content of intrusive noise. For façade thermal insulation, Sierra-Peréz et al. (2016) demonstrated how an optimized combination of elements could affect indoor thermal perception.

In this work, the acoustic and thermal insulation of a façade has been considered, varying the performance of single elements. 4 walls, 3 shutter systems and 5 windows. The acoustic performance was determined in a laboratory while the thermal performance was simulated from the thermal conductivity data, considering, in addition, linear thermal transmittance.

2. Calculation Models

The sound reduction index, $R$, of a building element is defined as:

$$ R = 10\log\left(\frac{1}{\tau}\right) $$

(1)

The transmission coefficient $\tau$ is the ratio of the sound power, $W_1$, which is incident on the test element to the sound power, $W_2$, radiated by the test element to the other side. $R$ was measured in laboratory conditions according to the ISO 10140 (2021) series standard:

$$ R = L_1 - L_2 + 10\log\left(\frac{S}{A}\right) $$

(2)

The composed sound reduction index, $R_{\text{tot}}$, was calculated as:
The weighted sound reduction index, $R_w$, and the spectrum adaptation term for pink noise, $C$, and for traffic noise, $C_{tr}$, were calculated according to ISO 717-1 (2020). The thermal conductivity, $\lambda$, of materials such as rock wool, EPS and XPS is measured according to EN 12667 standard (2021), while the thermal transmittance, $U$, and the linear thermal transmittance, $\psi$, were simulated by means of a FEM software according to ISO 10077-2 (2017) and ISO 10211 (2017) standards.

The composed thermal transmittance, $U_{tot}$, of the façade was obtained according to ISO 10077-1 (2017) with the following formula:

$$U_{tot} = \frac{\sum_{i=1}^{n} U_i S_i + \sum_{k=1}^{m} \psi_k l_k}{\sum_{i=1}^{n} S_i}$$  \hspace{1cm} (4)$$

### 3. Building Elements

The building elements considered are reported in Tables 1, 2 and 3.

Fig. 1 and 2 show the windows system for roller shutter used in the simulations. Window dimension was 1230 mm x 1480 mm, and wood frame thickness was 80 mm.

4. Acoustic Measurements and Thermal Simulations

The sound reduction index of the building elements was measured in the laboratory according to ISO 10140 (2021) series standard (Figs. 3, 4 and 5). The sound reduction index, $R$, of the building elements in the 1/3 octave frequency band is shown in Fig. 6. The weighted sound reduction and the thermal transmittance are shown in Table 4.

The thermal transmittance of the windows and window systems for roller shutters was simulated with FRAME SIMULATOR software.

From the thermal profiles in Fig. 7, it is possible to consider the “a” box shutter as the one with the best performance followed by “b” and “c”.

The linear thermal transmittances, $\psi$, of the shutter-wall interface, wall-window interface and shutter-window interface were calculated with Finite Element Method software MOLD SIMULATOR, according to ISO 10211 (2017). $\psi_1$ is the linear thermal transmittance for wall-shutter box, $\psi_2$ is the linear thermal transmittance for wall-shutter-window, $\psi_3$ is the linear thermal transmittance for shutter-window (Fig. 8 and Table 5).

Figs. 9, 10 and 11 show some temperature examples of linear thermal transmittance simulations.
Simulation of Thermal and Acoustic Façade Insulation Starting from the Characteristics of the Individual Elements

5. Results

The acoustic and thermal insulation of a 2.7-m-high and 4-m-wide façade has been considered. The composed weighted sound reduction index, \( R_w \), vs composed thermal transmittance, \( U \), is shown in Fig. 12. The composed weighted sound reduction index, \( R_w+C_t \), vs composed thermal transmittance, \( U \), is shown in Fig. 13. \( R_w+C_t \) considers weighted sound reduction index in dB(A) for traffic noise. The best configurations are located in the upper left quadrant.

It can be noted that there are no correlations between acoustic and thermal performance at all. Indeed, poor correlations are obtained even considering single wall results. For \( R_w \):

- \( R^2_{w,\text{wallA}} \) is 0.13;
- \( R^2_{w,\text{wallB}} \) is 0.41;
- \( R^2_{w,\text{wallC}} \) is 0.42;
- \( R^2_{w,\text{wallD}} \) is 0.15.

For \( R_w+C_t \):

- \( R^2_{w+C,\text{wallA}} \) is 0.09;
- \( R^2_{w+C,\text{wallB}} \) is 0.16;
- \( R^2_{w+C,\text{wallC}} \) is 0.18;
- \( R^2_{w+C,\text{wallD}} \) is 0.14.

Fig. 14 shows the configurations examined as the thermal transmittance, \( U \), decreases. In the same graph, the indices \( R_w \) and \( R_w+C_t \) are indicated (dotted line indicates the calculated transmittance without considering the linear thermal transmittance).
In Figs. 16 and 17, the overall acoustic performance is studied parametrically and compared to the wall ones. Interestingly, an important influence is assessed below 55 dB, while over this threshold no significant difference is found.

The influence of the shutter box transmittance is reported in Fig. 18. It is clear that shutters affect the final performance, but do not drive the overall final result because of their reduced area.
Moving on to the shutter box acoustic performances (Figs. 19-20), it can be seen that their influence affects overall results more when the wall provides high acoustic insulation.

The window parametric influence on overall results is depicted in Fig. 21.

When moving on to window acoustic parametric influence (Figs. 22-23), it can be highlighted that, when the sound insulation increases, the overall acoustic performance increases too. Again, this is due to window area, which is significant in the façades considered.

Here, it can be seen how, almost linearly, window thermal transmittances increase the overall final performances as expected because of their significant area.

Fig. 18 – Overall $U$ compared to the thermal transmittance of the shutter box, (a, b and c) $U_{\text{shutter}}$

Fig. 19 – Overall $R_w$ compared to the weighted sound reduction index of the shutter box (a, b and c), $R_w_{\text{shutter}}$

Fig. 22 – Overall $R_w$ compared to the weighted sound reduction index of the window (1, 2, 3, 4 and 5), $R_w_{\text{window}}$

Fig. 23 – Overall $R_w + C_w$ compared to the weighted sound reduction index of the window (1, 2, 3, 4 and 5), $(R_w + C_w)_{\text{window}}$
6. Conclusion

In this work, the acoustic and thermal insulation of 60 different combinations of façade elements was studied. 4 walls, 3 shutter systems and 5 windows were considered. It was possible to verify that there is no correlation between the overall final acoustic and thermal performances.

Some further considerations can be made:
- the best solutions from the thermal point of view are not the best ones from the acoustic point of view;
- the best combined thermal and acoustic performances are obtained using thermally insulating blocks (aerated concrete block) with internal lining and use of integrated window systems for roller shutters
- if linear thermal transmittance is not considered, considerable errors can be made (\(\Delta U=0.12-0.21\) W/(m²K)).
- it can finally be pointed out how, from a thermal point of view, all three elements equally contribute to the final performance, while, regarding acoustic insulation, the wall and the windows play a more important role due to their more extended area.
